

In this project, I aim to explore how online fashion trends influence the popularity of fashion products. With the increasing role of the internet and social media in shaping consumer preferences, trends reflected in online searches may have a direct impact on which clothing items become more common or widely available. I am interested in understanding whether there is a meaningful relationship between what people search for and the types of fashion products that appear in the market.

For this project, I plan to use a publicly available dataset from Kaggle that includes information about fashion products such as categories and product names. The dataset is expected to contain a large number of entries, which will allow for a meaningful analysis. To enrich this dataset, I will also collect trend data from Google Trends by selecting relevant fashion-related keywords and obtaining their popularity over time.

The data will be collected by downloading the dataset in CSV format and gathering trend data either manually or using Python tools such as `pytrends`. After combining the datasets, I will perform exploratory data analysis to observe patterns between trend popularity and product presence. I also plan to apply basic statistical methods and simple machine learning techniques to better understand and potentially predict how trends relate to fashion product popularity.
